Acute scrotal pain

Clinical history and physical examination

Suspected torsion
Suspected epididymo-orchitis/abscess

Ultrasound

History of trauma
Antecedent mass

Ultrasound

Equivocal

Nuclear medicine: testicular scan

Surgical exploration
Treatment

Treatment if hydrocele, haematocoele or testicular laceration etc.

CT abdomen and pelvis for tumor staging. CXR for suspected seminoma.
REMARKS

1 General
   1.1 For surgery to be successful, the diagnosis of acute torsion must be established within 4-8 hours from the onset of pain.
   1.2 Patients in whom there is strong clinical suspicion for testicular torsion can be promptly referred for scrotal exploration.

2 US
   2.1 The studies should include both the scrotum and inguinal areas.
   2.2 US can localize a scrotal swelling to see whether it is arising from the testis or from the epididymis and to distinguish a varicocele from a hydrocele.
   2.3 Colour Doppler US can reliably assess blood flow within the testis. Blood flow is markedly reduced or absent in torsion of testis but is increased in epididymo-orchitis. In adults, with careful study and appropriate equipment, the specificity is close to 100%. Overall sensitivity is about 90%. False negatives may be found in incomplete torsion (less than 180 degrees) and in spontaneous de-torsion. Colour Doppler US should be used in cases of suspected torsion or epididymo-orchitis.
   2.4 Imaging in clinically equivocal cases may lead to an early diagnosis of testicular torsion and thus decrease the number of unnecessary surgeries.

3 Nuclear medicine
   3.1 Testicular scan has 90% sensitivity and 98% specificity in assessing testicular torsion.
   3.2 Testicular scan is uncommonly requested nowadays given the high accuracy of US. It may be used when diagnosis is less likely and if torsion of the testis still cannot be excluded from history and physical examination. This should be done without inordinate delays for emergency intervention.
   3.3 Problems in examination performance may arise in infants and very small children whose genitalia are small and therefore difficult to image. Its poor anatomical detailing, and the time required for radionuclide scrotal imaging examinations are also limiting factors.

4 MRI
   4.1 Techniques are not typically used for the acute scrotum due to the limited availability of equipment and the long examination time involved. However, the use of MRI in scrotal diseases is increasing. A retrospective study reports that MRI has 93% sensitivity and 100% specificity for diagnosing testicular torsion.
   4.2 The most sensitive finding in torsion is decreased or lack of perfusion on dynamic contrast-enhanced MRI.
